## SANA MIGRATORY FISH COMMITTEE

## ANALYSIS OF SALMON AND SEA TROUT CATCHES TO DETERMINE THE TRUE IMPACT OF NETTING

Scottish rod catches of salmon and sea trout in 2020 were affected by a substantial period of Covid-related travel restrictions. The total for wild salmon catches was 45,366 and $93 \%$ were released. This is the third lowest total on record and $92 \%$ of the previous 5 -year average. While the figure was down a little on 2019 catches, it remained higher than the all time low point of 2018.
Each year's official catch statistics are examined by the Committee, so that they and SANA's members at large may be better informed. There are fewer netting stations in operation than hitherto and the moratorium on netting by fixed engines from 2016 has been extended indefinitely. Despite the known pressure on salmon stocks, commercial net fishing continued - with an increased catch, all from net and coble fisheries. There was no catch of salmon recorded by the Solway haaf netters.

While we have viewed net fishing as an important pressure on fish stocks, especially sea trout and spring salmon, it is now not mainly a Scottish problem. Rather, as noted below, we suspect that most impact of netting on stocks comes from killing of sea trout of Scottish origin by nets in the North East of England. In 2020, 21\% of salmon killed in Scotland were caught in nets -up from $14 \%$ in 2019.

Following lobbying, chiefly through SANA's participation in NASCO meetings, the North of England drift net fishery closed after the 2018 season. However, the North East of England fixed engines continued to operate from 2019, albeit with a requirement to return salmon. However, their wholesale slaughter of many thousands of Scottish sea trout remains a huge concern. Previous genetics research has shown that English nets impact on stocks in Scotland, especially sea trout. The numbers and the high average size of the sea trout indicate their killing of Scotland's broodstock on a grand scale. A proposed extension of the net season in 2020 was withdrawn by the Environment Agency, following representation by many bodies, including SANA.

Because of the Scottish ban on coastal nets from 2016, radical changes in the proportion of fish killed by nets could be expected. Indeed, that happened - but not initially to the extent that net catches were an insignificant proportion of those fish that are retained. In the case of the North Esk, in-river nets remained a significant pressure on stocks but did not operate from 2019. That made a big difference.

The substantial point is that net fisheries, except those undertaken for research purposes, are entirely lethal - their objective is to produce dead fish for sale. Rod fishers are prevented, by law, from killing early spring fish and have complied with voluntary as well as compulsory catch and release under Scottish Government conservation measures. Selling rod caught salmon and sea trout is illegal.
The analysis looks at the respective numbers of wild fish killed to provide food. The net catch had become a more significant pressure on stocks in recent years, especially for fragile spring stocks of early running fish - which for many anglers means from January to June. Because of the ban on coastal netting in 2016, there was considerable further easing. In 2020, nets accounted for a substantially increased pressure on stocks, accounting for $38 \%$ of spring salmon killed. (cf. $20 \%$ in 2019.) The rod catch and release rate for the January to June period stayed high, at $95 \%$.

For netting impact, the contrast between the early season and late season is now very marked. Nets accounted for $18 \%$ of fish killed after June. Considering the statutory obligations placed on anglers and their voluntary effort to limit impacts on stocks, the role of netting in the early season should also be treated as a conservation issue.
For sea trout, an increased share, $30 \%$ (cf. $26 \%$ in 2019) of fish killed in 2019 were retained by Scottish nets. This followed from lower net catches, much lower rod catches and a slightly higher rate of catch and release by anglers $88 \%$ (cf. $87 \%$ in 2019). The dominant net fishery was net and coble at $83 \%$ of the total (cf. $73 \%$ in 2019). There are few such operations left in Scotland. The North Esk net and coble fishery was dominant for salmon in 2018 and accounted for $71 \%$ of all net and coble sea trout catches in that year. However, the Scottish figures pale into insignificance, relative to net catches of sea trout in the North East of England.

Catch statistics from England and Wales are not up-to-date. North East of England net catches in 2019 were: Salmon and Grilse 129 ( 9,433 in 2018 and 9,909 in 2017); Sea Trout 13,673 (22,508 in 2018, 35,148 in 2017, 38,863 in 2016 and 60,696 in 2015). The sea trout average weight was not reported for 2018. Previous years were calculated at 2 kilograms ( 4.4 lbs ). This is a mixed stock fishery exploiting fish of unknown river origin, many of which are thought to be from river stocks in Scotland*. SANA prepared two submissions on this topic as part of a consultation on the future of this licensed fishery. Before the curtailment of these fisheries, announced in 2018, the number of licensed
nets was to have been reduced but the catch figures had suggested that the remaining nets became more efficient. A real and continuing drop in catches seems to be confirmed. However, the scale still represents a significant pressure on Scottish stocks.
An unattributed estimate has put the 2020 haul of sea trout by the North of England nets at 10,900 fish. Source: Trout and Salmon magazine.

## NUMBERS OF GAME FISH KILLED IN SCOTLAND - 2009 TO 2019

|  | Rod and Line | Nets | Total | Nets as \% of total |
| :---: | :---: | :---: | :---: | :---: |

*footnote: The first analysis of genotyping of catch samples was completed in respect of salmon: Genetic Investigation of the North East English Net Fisheries by John Gilbey, Lee Stradmeyer, Eef Cauwelier, Stuart Middlemas (Published 2012) Marine Scotland Science, Freshwater Laboratory, Faskally, Pitlochry, PH16 5LB. It says: "Assignment to region suggests that all NE English fisheries utilise a mixed stock resource, with between $40-80 \%$ of the captures being fish of Scottish origin, depending on the fishery. Drift nets have the highest proportion of Scottish captures, and T and J nets the lowest."
